When attempting to supply an External URL for the Advanced Outgoing API option on the Notifications/Custom Fields page, the following error is returned:

Advanced Outgoing API - Invalid URL:
The address portion of the URL http://your.example.com/url/listed/here.phpcould not successfully be loaded. You must be able to successfully load the URL in a browser in order to add it to the system
When adding a URL to the Advanced Outgoing API External URL field, Nanacast does a basic check to make sure the address is valid.
If you are getting this error, the issue is with the address in your URL. The address is the host/domain followed by the path to the file.

In this example, if *http://your.example.com/url/listed/here.php* doesn't load a page correctly (i.e., if it produces a server error), our system's check of the URL will fail.
Note: If you are adding variables to the API URL in a query (example: *
http://your.example.com/url/listed/here.php?value1={u_email}&value2={u_lastname}*) , the query portion of the URL-- the part after the question mark-- is NOT included in our system check. So when you are troubleshooting the address in your browser, you should remove the query (everything from the question mark to the end) and just test the address.
Until you are able to visit the address without your server producing a server error, our basic check will see this as not a valid URL.
